

Polar Bears, Frogs, Man and Global Warming by Christine Chesnais

Global warming has pros and cons about whether global warming is caused by things do or if its caused by the environment and nature's cycle. (There are many different causes of global warming that people have come up with.) First it is helpful to understand what global warming is.

What is global warming? Global warming is the increases in average temperatures in the Earth's atmosphere. Many people believe that global warming is caused by things that people do to the environment, such as doing greenhouse-gas activities, such as driving an air travel. An effect of global warming is that it affects animal species such as frogs. Global warming also causes the climate in certain places to be strange or unusual. Right now, an example of this is that the polar ice caps are melting a little, which is causing polar bears to die. "Most scientists agree that greenhouse-gas emissions are causing global warming, and that its rising temperatures are leading to the disappearance of Arctic ice, which is crucial to the health of the polar bear population." This will lead to polar bears dying because polar bears live on the ice, and without it, they can't survive. There are pros and cons of global warming also, and man's impact on it.

There are some pros and cons that have to do with global warming. There aren't many pros, but one pro is that it is causing people to be inspired to be more careful and clean with the environment. A con that has to do with global warming is that it's causing farm land to become rotten because the climate there is acting strange and causing many droughts in states with farmlands, such as Texas. Another con about global warming is that it is causing some animals to die since there is a lot of climate change in their habitats that they can't adapt to. Finally, one last con is that it is causing many weird weather patterns in many different places on Earth which may cause difficulties not just for animals but also for man.

Some people believe that man has been a major factor causing global warming. According to an article, "The IPCC (Intergovernmental Panel on Climate Change) and other scientific groups, such as the US National Academy of Sciences have reconfirmed that over the past decade that greenhouse-gas emissions from burning fossil fuels and deforestation, have led to a 1.4 degree rise in average global-surface temperatures world-wide in the past century." This is saying that many scientific groups in the USA have said that through the past decade, many greenhouse-gas emissions from the burning of fossil fuels and a lot of deforestation have led to a 1.4 degree rise in the average global-surface temperatures worldwide, throughout the past century. By doing greenhouse-gas activities, such as burning fossil fuels and engaging in deforestation, man has had an impact on global warming. Driving cars that use a lot of gas also is a way that man has affected on global warming.

Global warming is caused by many different things and has different effects on different things. It also has different pros and cons and many people debate whether if humans caused global warming or not.
